

context-object

A context-object is a JSON object, which contains a set of members which define the context of a request.

Usage

```
{
  "type": string,
  "parent": context-object,
  "uuid": string,
  "security": object
}
```

Members

"type": string, required

Specifies the type of context object this is. Based-on this value, other members within this object are implied. The types currently defined in this specification are: "[root](#)", "[http](#)" and "[resource](#)". Other context object types may be defined.

"parent": context-object or null, required

Contains the parent context, or null if the context is a [root-context](#) object.

"uuid": string, required

A string that contains a universally unique identifier, uniquely identifying the context. This is useful for tracing various activities as they traverse multiple resources and contexts.

"security": object, optional

Contains a set of security properties associated with the context.
